Despite increased recognition of the stress experienced by hospital nursing staffs and its effects on burnout, job satisfaction, turnover, and patient care, few instruments exist that can be used to measure stress. This paper describes the development of an instrument, the Nursing Stress Scale (NSS), along with the expanded Nursing Stress Scale (ENSS). The research population consisted of nurses working as formal contractual, provisional, and project employees at hospitals of Zabol. The sample consisted of 173 nurses. Research instruments included the Spiritual Experiences Scale for Students (developed by ghobari bonab kobasa), the Hardiness Questionnaire, and the expanded Nursing Stress Scale (ENSS). References include Alimoglu, M. K., & Donmez, L. (2005) Daylight exposure and the other predictors of burnout among expanded model of job satisfaction in a sample of registered nurses; Nursing Research, 59(6), 441-451; Donahue, L. (2009) A pod design for nursing assignments eliminating unnecessary steps and increasing stress scale. The level of occupational stress among a group of Indian staff nurses was measured using a questionnaire survey and professional stress scale and GHQ were applied in addition. Factors contributing to occupational stress were examined. Hospital nurses in this study reported moderate 51 to severe 3 levels of job-related stress.
an empirical evaluation of an expanded nursing stress scale journal of nursing gain further insights into the effect of frequently measurement occurring job related stressors over an extended period, the purpose of this study was to translate the nursing stress scale (NSS) into Chinese and test its reliability and validity among Chinese nurses in Taiwan. Potential participants were asked to self-administer a Chinese version of the NSS. The agreement estimation was used to determine the expanded nursing stress scale (ENSS) was used to measure nurses' job-related stressors. The ENSS is an expanded and updated revision of the classic nursing stress scale (NSS) developed by Gray, Toft, and Anderson in 1981. The original 34 items of the NSS measured the frequency and major sources of stress in patient care situations, personal determinants of nurses' burnout in end-of-life care, and the profession of nursing. This activity may differ when it comes to the type of patients more or less characteristic of each unit or sector of a hospital. J. Eyles' empirical evaluation of an expanded nursing stress scale, a nursing stress scale questionnaire is a written set of questions which are distributed amongst those people who belong to the profession of nursing. The aim behind framing such questionnaires is to know and analyse the level or scale of stress amongst nurses and other employees of the nursing unit of a medical centre. Validity and reliability of the Korean version of the expanded nursing stress scale (ENSS) was used to measure nurses' job-related stressors. The ENSS is an expanded and updated revision of the classic nursing stress scale (NSS) developed by Gray, Toft, and Anderson in 1981. The NSS was the first instrument to target nursing stress rather than general job stress, despite increased recognition of the stress experienced by hospital nursing staffs and its effects on burnout, job satisfaction, turnover, and patient care. Few instruments exist that can be used to measure stress. This paper describes the development of an instrument, the nursing stress scale (NSS), the expanded nursing stress scale (ENSS). This scale was used to assess occupational stress in nurses. It is an expanded version of the original 34-item nursing stress scale. occupational stress exists in every profession nevertheless the nursing profession appears to experience more stress at work compared to other health care workers unmanaged stress leads to high levels of employee dissatisfaction illness absenteeism high turnover and decreased productivity that compromise provision of quality service to clients, questionnaires were administered to nurses at yearly intervals to measure stress expanded nursing stress scale 22 burnout maslach burnout inventory 23 professionalism in the nicu professional practice environment scale 24 and family centered care survey 18 we also measured medical practices every 6 months, the level of occupational stress among a group of indian staff nurses was measured using a questionnaire survey and professional stress scale and ghq were applied in addition factors contributing to occupational stress were examined hospital nurses in this study reported moderate 51 to severe 3 levels of job related stress, in the study of work related stress among nurses the nursing stress scale nss is the best known and most widely used scale this article presents an overview of the nss and its use and describes the development of an expanded instrument enss to measure sources and frequency of stress perceived by nurses findings are based on a random sample of 2 280 nurses in ontario working in a wide, stress level among staff members was measured using the expanded nursing stress scale enss prior to commencing nurses education and again at the end of 18 weeks of nurses education 18 enss is a well known and widely used scale to measure work related stress among nurses 18 it had been validated to measure sources and frequency of stress, stress and stressors in the clinical environment a comparative study of fourth year student nurses and newly qualified general nurses in ireland a thesis presented to dublin city university for the masters degree in science by patricia suresh rnid rgn bns hons id number 52173232 dublin city university school of nursing january 2009, occupational stress the expanded nursing stress scale enss for the in vestigation of nurses work related stress is one of the most widely used scales which has already been adapted and validated in greek and developed by gray toft amp anderson 15 it incorporates 59 items with 9 subscales each item requires respondents to rate on a five point, nurses a study was conducted on 100 staff nurses modified expanded nurses stress scale was used and requires 15 30 min to salve for each questionnaire majority 49 of nurses had reported frequent occurrence of stress due to uncertainty of
concerning treatment, stress level among staff members was measured using the expanded nursing stress scale (ENSS) prior to commencing nurses education and again at the end of 18 weeks of nurses education. ENSS is a well-known and widely used scale to measure work-related stress among nurses. It had been validated to measure sources and frequency of stress, the nurses were interviewed by a questionnaire including expanded nursing stress Likert scale and the main factors that contribute to work-related stress data were managed by statistical package for social science version 20. Results of overall occupational stress experienced by nurses was 1.88 with standard deviation of 0.50. Stress among the nurses working in intensive care units in selected hospitals of Navimumbai with a view to develop an health educational pamphlet on stress management. Simple random sampling technique was used for the selection of 50 ICU staff nurses. The researcher modified the expanded nursing stress scale to assess the level of stress, the instrument used to collect data was expanded nursing stress scale. Grey, Toft, and Anderson (1981) developed this scale, which has 59 items grouped under nine subscales. The subscales measure stress related to death and dying, conflict with physicians, inadequate preparation, family issues, problems with colleagues, job-related stress, aspects of your job that cause stress, managing stress, and problems related to stress. The questionnaire was expanded to include specific job professionals who happened to join the same stress management-related stress questions and aspects of your job that cause stress. Groups of these occupational groups were administered the stress questionnaire. The most recent conflict stress questionnaires on a, Jewell, and Siegalls (1990) nurse stress index correlated stress scores with job satisfaction. Not behavioral aspects. It aimed to identify issues of occupational stress. Stordeur, Dhooere, and Vandenberghe (2001) used a nursing stress scale which identified three sources of stress: physical, psychological, and social environments. Tool I, the ENSS is an expanded and updated revision of the classic nursing stress scale (NSS) developed by Grey, Toft, and Anderson (1981). French, Lenton, Walters, and Eyles (2000) used the original 34 items of the NSS to measure the frequency and major sources of stress by nurses in hospital units. The NSS was the first instrument to target nursing stress rather than general job stress. The original 34 items of the NSS measured the frequency and major sources of stress by nurses on responses to the
Expanded nursing stress scale (ENSS) identified that the new registered nurses rated their uncertainty concerning treatment as highly stressful events that frequently occurred in the workplace. The study findings also revealed that the level of stress and the common stressors in new registered nurses within the first three months were highly stressful. The purpose of this study was to translate the nursing stress scale (NSS) into Chinese and test its reliability and validity among Chinese nurses in Taiwan. Potential participants were asked to self-administer a Chinese version of the NSS. The agreement estimation was used to determine the reliability of the translated scale. The nurses were interviewed by a questionnaire including an expanded nursing stress Likert scale and the main factors that contribute to work-related stress. Data was managed by the statistical package for social science version 20. Results showed that the mean score of overall occupational stress experienced by nurses was 1.88 with a standard deviation of 0.50. The expanded nursing stress scale (ENSS) was used. A total of 187 nurses completed the questionnaire. The stress experienced by nurses depends on the team. The study results reveal both individual and team-level stress. The effect of the team size is moderate, but the background factors of the teams had little association with the sub-scale. Team-related factors associated with stress have been identified as team climate, supportive colleagues, and work environment. A descriptive study was conducted among nurses from 29 teams in 18 different primary health care centers located in one Lithuanian county. The expanded nursing stress scale (ENSS) was used. There will be a one-week period of no exposure, and the interventions switched the outcome measures that will be observed include morning blood pressure surge, evening blood pressure decline, salivary cortisol, expanded nursing stress scale score, state-trait anxiety score, profile of mood state score, and Pittsburgh sleep quality index score. An empirical evaluation of an expanded nursing stress scale journal of nursing gain further insights into the effect of frequently measurement. The expanded nursing stress scale was used to evaluate the study data. The study indicates that in primary healthcare centers, nurses working with adult patients experienced less stress than those working with younger patients. The most frequently reported stressors were those related to death and dying and conflicts with physicians. An empirical evaluation of an expanded nursing stress scale journal of nursing 2000. Susan French, Rhonda Lenton, John Eyles. Download with Google, Facebook, or Email. An empirical evaluation of an expanded nursing stress scale journal of nursing. The nursing stress scale (NSS) is the best known and most widely used scale. This article presents an overview of the NSS and its use and describes the development of an expanded instrument (ENSS) to measure sources and frequency of stress perceived by nurses. Findings are based on a random sample of 2,280 nurses in Ontario working in a wide range of settings, including intensive care units. The ENSS was used to measure any situations perceived by the participants as threatening because of a mismatch between the situation demands and the individuals' coping abilities. The job satisfaction survey (JSS) was 36 items, nine facet scales to assess, of stress among the nurses working in intensive care units.
